

The EHR that documents itself

Therapists lose 15–20 minutes per session to notes — typed from memory, hours after the detail has faded. Kith listens during the session and turns it into a structured clinical note automatically, so documentation stops competing with client time.

How it works

Ambient transcription captures the session — in person via the device mic, or online through a notetaker bot that joins the Google Meet call. A two-layer AI pipeline (one pass compresses the transcript, a second structures it) turns that into a SOAP, DAP, or BIRP note, pulling the last four sessions in for continuity — summary, homework, next-session plan, and anything that never got followed up on.

What's in the free plan — no card required

- Ambient transcription, in-person and online (Deepgram + Google Meet notetaker bot)
- AI note pipeline: SOAP / DAP / BIRP, drafted automatically from the session
- Separate consent gates for recording vs. AI processing — not one bundled checkbox
- Conflict-checked scheduling, recurring appointments, auto-generated Meet links
- Patient records with CSV/Excel import, and PDF export so notes outlive the software
- DPDP-2023 / GDPR-aligned field encryption, per-therapist row-level security

Who it's for

Solo and small-practice therapists in India and the UK who currently write notes after hours, juggle a separate scheduler and EHR, or re-type patient rosters every time they switch tools — and want documentation handled without a paid seat for every clinician.
